MAAS PROJECTS

FLYING SAUCERS BAKERY

- ▶ We model a typical German bakery.
- ▶ The bakery offers a number of different products.
- ▶ The bakery has numerous customers.
- ▶ The bakery delivers products via a number of trucks.
- ▶ We look at order processing, the production process, and product delivery

FLYING SAUCERS BAKERY: ORDER PROCESSING

- ▶ Some customers (mainly sales shops, supermarkets) order between 50% and 100% of their demand at end of the day before delivery (next day orders). The remaining demand is ordered on the same day as delivery.
- ▶ Some customers (elderly homes, hospitals, canteens) order all their demand once a day for next day delivery.
- ▶ Some customers (catering services, clubs, associations, etc. organising special events) order their demand several days ahead of delivery.
- ▶ To guarantee freshness, products can only be produced on the day of delivery.

FLYING SAUCERS BAKERY: FORMALIZING ORDER PROCESSING

- ▶ We work on a common system clock $\langle ddd.hh \rangle$ consisting of a day number and an hour. E.g. delivery at $\langle 12.04 \rangle$ means that an order must be delivered on day 12 no later than the end of hour 04.
- ▶ An order consists of the following information:
 - ▶ A customer id
 - ▶ An order date (day and time at which the order is released)
 - ▶ A delivery date (day and time at which the order must latest be delivered)
 - ▶ A vector over the range of products with the # of items ordered
- ▶ Example: ["WhizKidSchool", $\langle 11.16 \rangle$, $\langle 12.09 \rangle$, [100, 120, 0, 0, ...]]

FLYING SAUCERS BAKERY: PRODUCTION PROCESS

- ▶ The production of a product of the bakery follows this process:
 - ▶ First, the dough must be prepared in a kneading machine. This takes a certain dough preparation time, which is independent of the number of product items.
 - ▶ Next, the dough must rest. This takes a certain resting time.
 - ▶ Next, the dough must be prepared for baking. This takes a certain item preparation time for EACH item.
 - ▶ Next, the product must be baked. This takes a certain baking time.
 - ▶ After baking, the product must cool before it can be boxed and delivered. The minimal cooling time is proportional to (baking temperature minus 40° Celsius).

FLYING SAUCERS BAKERY: PRODUCTION PROCESS

- ▶ Further details and constraints of the production process:
 - ▶ The bakery has a number of ovens, each of which has 4 equally-sized baking slots with individual controllable baking temperature.
 - ▶ Changing the baking temperature requires time for adjustment, proportional to the temperature difference.
 - ▶ For each product, a number of items simultaneously fit into an oven slot.
 - ▶ Slots are always filled only with items of a single product. In/out same time.
 - ▶ There is a limited number of dough preparation machines and item preparation work places.
 - ▶ For now, we assume no constraints on storage areas for
 - ▶ resting dough and
 - ▶ items cooling after baking.
 - ▶ A production shift lasts from midnight to lunch <ddd.00> – <ddd.12>

FLYING SAUCERS BAKERY: FORMALIZING PRODUCT INFORMATION

▶ Product Information:

- ▶ product id
- ▶ dough prep time
- ▶ resting period
- ▶ item prep time
- ▶ # of items fitting in oven slot
- ▶ baking time
- ▶ baking temperature
- ▶ boxing temperature
- ▶ cooling time factor (in sec/°C)
- ▶ # of items fitting into a box
- ▶ production cost
- ▶ sales price

FLYING SAUCERS BAKERY: FORMALIZING THE PRODUCTION PROCESS

- ▶ Factory information:
 - ▶ number of dough kneading machines
 - ▶ number of ovens
 - ▶ oven heating time factor (sec/°C)
 - ▶ oven cooling time factor (sec/°C)

FLYING SAUCERS BAKERY: PRODUCT DELIVERY

- ▶ The bakery delivers the products on or before the due date to its customers, using a number of trucks.
- ▶ For transport and delivery, products are boxed. For each product, a certain number of items fit into a box. Only items of same kind in a box.
- ▶ Trucks can transport a maximum number of boxes per tour.
- ▶ Trucks, customers, and the bakery have a location $\langle x, y \rangle$.
- ▶ A street network is defined by a set of labeled direct connections between locations of customers, and the bakery. The labels correspond to distance.

FLYING SAUCERS BAKERY: FORMALIZING PRODUCT DELIVERY

- ▶ Packaging information: associating the order vector $[100, 120, 0, 0, \dots]$ with a box vector $[2, 3, 0, 0, \dots]$
- ▶ Information on trucks:
 - ▶ truck ID
 - ▶ load capacity (maximum number of boxes)
 - ▶ load: a list of modified orders (item vector replaced by box vector)
 - ▶ location
- ▶ Street network: as a labeled graph of vertices V and edges E where
 - ▶ the set of vertices V contains all customers and the bakery
 - ▶ the set of edges E is a subset of $V \times V \times \mathbb{R}^+$
 - ▶ Note: for vertices a, b , two edges (a, b, x) and (b, a, y) with $x \neq y$ may be defined

PROJECT WORK: FIRST STEPS

- ▶ Get acquainted with the implementation platform:
 - ▶ Download and install software
 - ▶ Check correct installation
 - ▶ Consult documentation
 - ▶ Work through tutorial
- ▶ Create some toy example:
 - ▶ Create three to four agents
 - ▶ Let them exchange (send and respond to) some messages

PROJECT WORK: SECOND STEPS

- ▶ In our scenario, focus on the order processing first:
 - ▶ You want to create agents representing customers:
 - ▶ These agents should be able to read a schedule of orders from a file.
 - ▶ They need to send these orders to the bakery agent at the right time.
 - ▶ You probably also want to have an agent representing the bakery:
 - ▶ This agent should take the orders for customers and store them in some appropriate way.
 - ▶ Agents to be implemented later (for production and delivery) may want to know:
 - ▶ An aggregation of a customer's orders for each day or each date <ddd.hh>
 - ▶ An aggregation of all orders for a particular product for each day or each date
 - ▶ Think of other kinds of aggregations and how to represent them.
 - ▶ Discuss whether you need additional agents. If yes, what for.
- ▶ Implement and test your multiagent system.

branches:

- master → stable
 - develop → test here first, then merge
 - feature / add - book seller
 - fix / bug - in - book - seller
- 
- ```
graph LR; feature[feature / add - book seller] --> develop[develop]; fix[fix / bug - in - book - seller] --> develop;
```
- The diagram illustrates the merge process. Two arrows originate from the 'feature / add - book seller' and 'fix / bug - in - book - seller' branches, pointing upwards and then rightwards to merge into the 'develop' branch.

# MAAS PROJECTS:

- order is object for naming info
- Customer
- order processing
- delivery
- system clock
- scheduler
- Virtualization agent

## Stages:

- Bakery
- order processing
  - dough prep
  - baking and cooling
  - packaging and loading
  - delivery

// How to process order?

// What is an agent, what is an agent?

// order processing interface

// An object isn't able to do smth. by itself

// orders have a lifecycle

// common

Over as agent (heating etc.

- Auftrag als Agent  
modelliere - wann kommt  
mit a wann bis ist fertig

Scheduler als zentrale Instanz

Ofen als Agent nehmen

- 1 Customer Agent

Ein globaler Agent für System Clock

Künetmaschine als Agent

Luftwaage als Agent

z.B. 10 B 2 Mi für Festlegung
